Abstract

The paper contains critical comments to the paper mentioned in the title from the mathematical point of view.

The following remarks refer to the paper mentioned in the title. In the following it is quoted as [R]. They concern the pure mathematical point of view. There are critical comments to special points (3,4,5) of that paper and to statements which could cause misunderstandings. The paper contains even bad mistakes. This special critique leads to the conclusion that the paper fails its own aim in the following sense: The author of these remarks agrees completely with the following statements of Rafael de la Madrid in the introduction of his paper,

- "... the resonance states and time asymmetry can be achieved within standard quantum mechanics."
- "...the content of the Hardy axiom is not a matter of assumption, but a matter of proof."

Now first the comment to point 3 shows that the "Hardy axiom" can be proved rigorously within the framework of standard quantum mechanics, i.e. well-understood it is not an axiom but a fact, a theorem. Second, the comments to point 4 suggest that, mathematically speaking, "time asymmetry" is an intrinsic element of the mathematical apparatus of standard quantum mechanics which is finally due to the semiboundedness of the Hamiltonians and the property that their absolutely continuous spectrum is of homogeneous multiplicity and (in general) coincides with the positive half line. Independently of the special shape of what Rafael de la Madrid calls "Bohm-Gadella theory" and of special objections one can have against it (cf. for example the remark in this letter concerning the extensive use of the Lippman-Schwinger equation in this connection) it seems to be a merit of Bohm and Gadella to have perceived that the Hardy spaces are decisive for these connections, which obviously do not leave the framework of standard quantum mechanics.

To begin with the context let H be the selfadjoint operator on the Hilbert space $\mathcal{H}_+ := L^2(0, \infty)$ given by the differential expression

$$(Hf)(r) := -\frac{d^2f}{dr^2}(r) + V(r)f(r), \quad f \in \mathcal{H}_+,$$

together with the boundary condition f(0) = 0, where V is real-valued, locally integrable, V(r) = 0 for r > R > 0 and $\int_0^R r|V(r)|dr < \infty$. If $V(r) \ge 0$ then H has no eigenvalues. The case in [R] is a special case of this setting. Further let H_0 be the selfadjoint operator of the same type but with V = 0. The wave operators

$$W_{+} := \text{s-lim}_{t \to +\infty} e^{itH} e^{-itH_0}$$

exist and they are asymptotically complete. Let $r \to \phi(r, E)$ be the so-called regular solution of the differential equation

$$-\frac{d^2y}{dr^2}(r) + V(r)y(r) = Ey(r), \quad \phi(0, E) = 0, \ \phi'(0, E) = 1,$$

and $\phi_0(\cdot, E)$ the corresponding solution for V = 0. ϕ is an entire function in E, for example $\phi_0(r, E) = \frac{\sin \sqrt{E}r}{\sqrt{E}}$. For the calculation of the corresponding unitary canonical spectral representations of H and H_0 one has to use the so-called Jost functions $A_{\pm}(\cdot)$, given by

$$\phi(r, E) = A_{-}(E)e^{i\sqrt{E}r} + A_{+}(E)e^{-i\sqrt{E}r}, \quad r > R, E > 0.$$

For example, for ϕ_0 one has $A_-(E) = \frac{1}{2i\sqrt{E}}$, $A_+(E) = -\frac{1}{2i\sqrt{E}}$. Then

$$\mathcal{H}_{+} \ni f \to \Psi f \in \mathcal{H}_{+} : (\Psi f)(E) := \frac{1}{2\sqrt{\pi}E^{1/4}|A_{+}(E)|} \int_{0}^{\infty} \phi(r, E)f(r)dr$$

and

$$(\Psi_0 f)(E) := \frac{E^{1/4}}{\sqrt{\pi}} \int_0^\infty \phi_0(r, E) f(r) dr,$$

such that

$$\Psi(e^{-itH}f)(E) = e^{-itE}(\Psi f)(E), \quad \Psi_0(e^{-itH_0}f)(E) = e^{-itE}(\Psi_0 f)(E).$$

For convience we denote the multiplication operator $g(E) \to Eg(E)$, $g \in \mathcal{H}_0$ by M. For the (unitary) inverse transformations Ψ^{-1} , Ψ_0^{-1} one obtains

$$(\Psi^{-1}g)(r) = \frac{1}{2\sqrt{\pi}} \int_0^\infty \phi(r, E)g(E) \frac{1}{E^{1/4}|A_+(E)|} dE, \quad g \in \mathcal{H}_+, \tag{1}$$

$$(\Psi_0^{-1}g)(r) = \frac{1}{\sqrt{\pi}} \int_0^\infty \frac{\sin(\sqrt{E}r)}{E^{1/4}} g(E) dE, \quad g \in \mathcal{H}_+.$$

W.r.t. the canonical spectral representations the wave operators W_{\pm} act by wave matrices $E \to W_{\pm}(E)$ as multiplication operators, defined by $\Psi W_{\pm} \Psi_0^{-1}$.

The so-called Lippman-Schwinger equation yields an equation for the wave matrices which is of limited value for concrete calculations, in general. (Also for this reason it is not recommendable to use this equation as a starting point for proposals of new postulates with a deeper conceptional aspect.) Using the formula

$$W_{\pm}f = \pm i \operatorname{s-lim}_{\epsilon \to +0} \int_0^\infty E(d\lambda)(\epsilon R_0(\lambda \pm i\epsilon))f,$$

for the wave operators where $E(\cdot)$ denotes the spectral measure of H and $R_0(z) := (z - H_0)^{-1}$ the resolvent of H_0 , one obtains for the wave matrices

$$W_{\pm}(E) = \mp i \frac{A_{\pm}(E)}{|A_{+}(E)|}, \quad E > 0,$$

i.e. the wave matrices coincide (up to a normalization factor) with the Jost functions. Considering \mathcal{H}_+ as the space of the spectral representation of H and putting

$$\Phi_{\pm} := P_{+}\mathcal{H}_{+}^{2} \subset \mathcal{H}_{+},$$

where $\mathcal{H}_{\pm}^2 \subset \mathcal{H} := L^2(\mathbb{R})$ denote the Hardy spaces w.r.t. the upper resp. lower half plane and P_+ the projection by multiplication with the characteristic function $\chi_{[0,\infty)}$ such that $\mathcal{H}_+ = P_+\mathcal{H}$, then it turns out that Φ_\pm is a dense linear manifold in \mathcal{H}_+ and $\tilde{\Phi}_\pm := \Psi^{-1}\Phi_\pm$ is dense in \mathcal{H}_+ , i.e. each "radial function" $f_\pm \in \tilde{\Phi}_\pm$ gives via Ψf_\pm the "positive part" of a Hardy function in \mathcal{H}_+ , considered as the space of the spectral representation of H. Conversely, if the positive part of a Hardy function is given, the corresponding "radial function" can be calculated by (1). This is a comment to point 3 of [R]. It shows that - in contradiction to the assertion of Rafael de la Madrid that "the limits (2.18) and (2.19) are in general not zero" - there is a dense set of radial functions from $L^2(0,\infty)$ (wave functions) which produce a (dense) set of positive parts of Hardy functions in the spectral representation space (again $L^2(0,\infty)$), in particular a dense set which are additionally Schwartz functions. Therefore, the conclusion of "inconsistency" in [R] is nonsense.

The dense manifolds Φ_{\pm} are not invariant w.r.t. e^{-itM} , in general. However Φ_{+} is invariant for $t \leq 0$ and Φ_{-} is invariant for $t \geq 0$.

The multiplication operator M: Mf(E) = Ef(E) can be extended to the whole space \mathcal{H} such that

$$\mathcal{H} \ni q \to e^{-itM}q : e^{-itM}q(E) = e^{-itE}q(E).$$

Note that for the extended (spectral) evolution the subspaces \mathcal{H}^2_{\pm} are invariant for t < 0 resp. t > 0. Now e^{-itM} is the Fourier transform of the shift transformation T(t) on \mathcal{H} , T(t)g(x) := g(x-t), i.e.

$$F^{-1}e^{-itM}F = T(t),$$

where the Fourier transformation is given by

$$Fg(E) := \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-iEx} g(x) dx.$$

Note that

$$F^{-1}Q_{\pm}F = P_{\mp},$$

where Q_{\pm} is the projection onto the Hardy space \mathcal{H}_{\pm}^2 and P_{-} the projection by multiplication with the characteristic function $\chi_{(-\infty,0]}(\cdot)$. $P_{\mp}\mathcal{H}$ are the wellknown incoming/outgoing subspaces of the shift evolution T(t). The connection between the evolution e^{-itH} and T(t) is then given by

$$e^{-itH} = \Psi^{-1}P_{+}FT(t)F^{-1}P_{+}\Psi$$

and the invariant manifolds for t > 0, t < 0 are

$$\Psi^{-1}\Phi_{\mp} = \Psi^{-1}P_{+}\mathcal{H}_{\pm}^{2} = \Psi^{-1}P_{+}FP_{\pm}\mathcal{H},$$

i.e. $f_{\pm} \in \Psi^{-1}\Phi_{\mp}$ is given by $f_{\pm} = \Psi^{-1}P_{+}Fg_{\pm}$ where $g_{\pm} \in P_{\pm}\mathcal{H}$, that is g_{\pm} are outgoing/incoming vectors w.r.t. the shift evolution. The correspondence $f_{\pm} \leftrightarrow g_{\pm}$ is a bijection so that g_{\pm} can be considered as a representer of f_{\pm} . In other words, $g_{\pm} = F^{-1}\Psi(f_{\pm})$ or

$$g_{\pm}(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{ixE} (\Psi f_{\pm})(E) dE$$

This comments point 4 in [R]. The functions in equations (4.5), (4.8) are the representers g_{\mp} of the elements f_{\mp} which are from the invariant manifolds w.r.t. the "real" evolution e^{-itH} . Obviously in [R] there is a confusion between the parameter t of the evolution and the variable in the argument of the functions where the shift evolution acts (e.g. in (4.5)) which is denoted by x in the comment. (Already the "conclusion" equation (4.9) should suggest that something is wrong in the starting statement.)

The statement in point 5: "... Hardy functions are not suitable for systems whose spectrum is bounded from below" is definitely wrong. On the contrary, they seem to be decisive for the connection of the "Gamov vectors", which are special eigenvectors of the so-called "decay semigroup" of the Toeplitz type, to the eigenlinear forms of the resonances if their spectral theoretical characterization w.r.t. the quantum mechanical evolution is established. For example, in the case of the finite-dimensional Friedrichs model on the positive half line this is pointed out in [1] (see also [2]).
